# Lesson 3

# Data Structures and Algorithms DSA

#### In this lesson we will talk about:

- ▶ data structures
- ► algorithm design
- ► algorithm efficiency
- searching and sorting algorithms

# **Data Structures**

# What is a data structure?

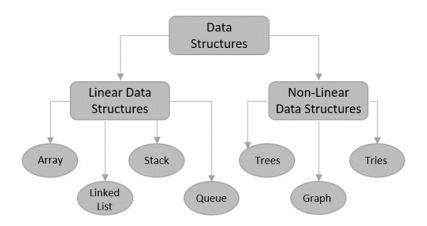

In computer science, a **data structure** is a data organization and storage format that is usually chosen for efficient access to data. [1][2][3] More precisely, a data structure is a collection of data values, the relationships among them, and the functions or operations that can be applied to the data, [4] i.e., it is an algebraic structure about data.

#### **Data Structures**

- ► How do we **organize** data
- ► For a very **efficient** access

It's a collection of data values, and the relationships among these values

#### **Data Structures**

# Linear Data Structures: Arrays, Queues, Stacks

- ► Elements are arranged sequentially, one after the other
- ➤ The first element added will be the first one to be accessed or removed, and the last element added will be the last one to be accessed or removed
- ► Can have either fixed or dynamic sizes
- Offer very efficient data access

## Non-linear Data Structures: Trees, Graphs

- ► Elements are arranged hierarchical
- ▶ We cant traverse all the elements in a single run only
- ► There are multiple levels which we must traverse
- ▶ It is more difficult to implement

#### **Data structures**

- ► Sets
- ► Arrays and Matrices
- ► Stacks
- Queues
- ► Linked lists
- ► Trees
- ► Graphs

# Sets

#### Sets

A set is usually a **collection** of different things, fixed in size. Sets can also change size, usually when an algorithm will perform modifications against the set. We call these dynamic sets. These sets can change in size, grow or shrink, basically change over the time.

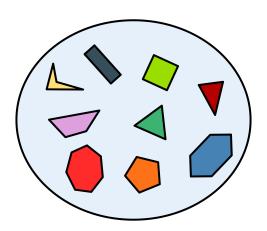

But what is a set?

#### Sets

The basic, fundamental data structure:  $\{1,2,4,51,9\}$ 

- mathematical set
- unchanging, unique elements, no duplicates
- contains a fixed number of elements: finite set
- ▶ or it can contain an infinite number of elements

# For example a set of polygons

#### Sets

A set is a **mathematical model** of a collection of different things. A set contains elements or members, which can be mathematical objects of any kind numbers, symbols, points in space, lines, other geometrical shapes, variables, or even other sets.

## Sets, examples

- ► {white, blue, red, yellow}
- ► The empty set {}
- ▶ Natural numbers:  $\mathbb{N} = \{0, 1, 2, 3, \ldots\}$
- ▶ Natural numbers except 0:  $\mathbb{N}^* = \{1, 2, 3, ...\}$
- ► Integers:  $\mathbb{Z} = \{\ldots, -3, -2, -1, 0, 1, 2, 3, \ldots\}$
- ▶ Positive integers:  $\mathbb{Z}_+ = \{0, 1, 2, 3, \ldots\}$

# $\{1,2,3,4\}$

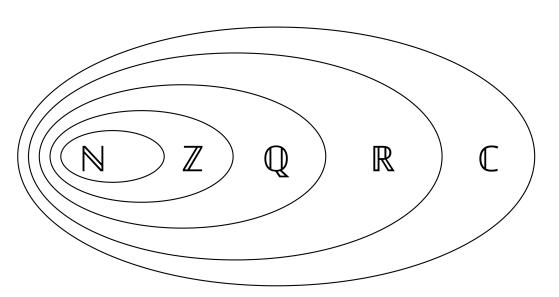

Defines a list of elements, using a simple enumeration notation (Roster notation) between curly brackets, separated by commas.

#### **Basic Operations on Sets**

- ► Insert add a new element to a set
- ▶ Delete remove an element from a set
- ► Test if element X belongs to a set or not

A dynamic set which supports all these basic operations: **a dictionary** 

Natural Numbers (Counting Numbers) (N)	Numbers you use for counting: 1, 2, 3	It's "natural" to count on your fingers: 1, 2, 3,	
Whole Numbers	The natural numbers, plus 0: 0, 1, 2, 3	The word "whole" has an "o" in it, so include 0.	
Integers (Z)	Whole numbers, their opposites (negatives), plus 0:2, -1, 0, 1, 2	Integers can be separated into negative, 0, and positive numbers.	
Rationals (Q)	Integers and all fractions, positive and negative, formed from integers. These include repeating fractions, such as $\frac{1}{3}$ , or .33333 or $\overline{3}$ .	The word "rational" is a derivation of "ratio", and rational numbers are numbers that can be written as a ratio of two integers. "Q" stands for quotient.	
Irrationals	Numbers that cannot be expressed as a fraction, such as $\pi$ , $\sqrt{2}$ , e. (We'll learn about these later).	If something is "irrational", it's not easy to explain or understand.	
Real Numbers (配)	Rational numbers and Irrational Numbers. The real number system can be represented on a number line: $-\infty5  0  .5  1  \sqrt{2}  2  \infty$	If a number exists on a number line that you can see it must be "real". Note that the "smallest" real number is negative (–) infinity ( $-\infty$ ), and the largest real number is infinity ( $\infty$ ). We can never really get to these "numbers" ( $-\infty$ and $\infty$ ), but we can indicate them as the "end" of the real numbers.	
Complex Numbers	Real numbers, plus imaginary numbers (concept only, such as $\sqrt{-2}$ ).	"Imaginary" numbers are difficult to imagine, since they are so "complex".	

# **Advantages**

Perform operations on a collection of elements in a very **efficient** and **organized** manner

#### **Conclusions**

Sets are basic, fundamental data structures, with:

- ▶ unique elements
- ▶ no duplicates
- unchanging
- ▶ fixed or infinite number of elements

Im confused. Does it mean a set is similar to a Python set? Or what is the difference?

# Sets vs. Python Set

In computer science (CS), a set is an abstract data type that can store unique values, without any particular order. It is a computer implementation of the mathematical concept of a finite set.

## Mathematical vs. Python Sets

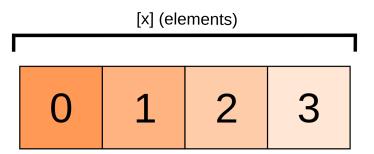

- ► Mathematical finite set: {1,2,3,4}
- ▶ Python set:  $S = \{1,2,3,4\}$

# Arrays

## **Arrays**

In computer science, an **array** is a data structure consisting of a collection of elements, each identified by an **index** or a **key**. The simplest type of such data structure is a linear array, the one-dimensional array.

#### Typical "1 Dimensional" array

Element indexes are typically defined in the format [x] [x] being the number of elements

For example: this array could be defined as array[4]

## **Arrays**

Arrays are among the oldest and most important data structures, and are used by almost every program and programming language. They are also used to implement many other data structures, such as lists.

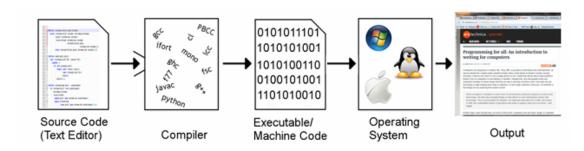

# **Arrays**

Arrays are useful because the element indices can be computed at run time. Among other things, this feature allows a single iterative statement to process arbitrarily many elements of an array. For that reason, the elements of an array data structure are required to have the same size and should use the same data representation.

#### Run-time?

Runtime, run time, or execution time is the final phase of a computer program's life cycle, in which the code is being executed on the computer's central processing unit (CPU) as machine code. In other words, "runtime" is the running phase of a program.

#### Remember this? From source code to executable

# **Basic Array Operations**

- ► traversal of an array
- ► access element X in an array
- searching element X in an array
- sorting an array

#### **Example 1: Traversing the array A**

#### Example 2: Find the max value in the array A

```
1: procedure MAXARRAY(A)

    Returns the max value in A

      N \leftarrow length(A)
      MAX \leftarrow A[0]
3:
       for from i=1 to N-1 do
4:
          if A[i] > MAX then
5:
              MAX = A[i]

    The MAX is A[i]

6:
          end if
7:
       end for
8:
       return MAX
9:
10: end procedure
```

#### Example 3: Search element X in array A

```
1: procedure SEARCHARRAY(A) \triangleright Returns the max value in A
       X \leftarrow MyElement
       N \leftarrow length(A)
3:
       for from i=0 to N-1 do
4:
          if X = A[i] then
5:
               return i
                                           > The index for my match
6:
           end if
7:
       end for
8:

    otherwise return -1

       return -1
9:
10: end procedure
```

#### There are numerous applications of arrays

- ► Storing data in databases. Storing a list of customer names.
- ► Traffic Management. Traffic management systems use arrays to track vehicles and their flow. By analyzing data stored in arrays, traffic control centers can implement efficient signal timings and manage congestion effectively.

- ▶ Financial Analysis. It keeps track of various financial instruments, including stocks, bonds, and mutual funds. By organizing data in arrays, companies can perform analyses and make predictions easier
- ► Machine Learning. Machine learning algorithms often accept arrays as input, helping to train models and make predictions.

# Matrices

#### What is a matrix?

In mathematics, a matrix (pl.: matrices) is a rectangular array or table of numbers, symbols, or expressions, with elements or entries arranged in rows and columns, which is used to represent a mathematical object or property of such an object.

#### **Matrices**

Typical "2 Dimensional" array

[x] (rows)

				<u>'</u> –
00	01	02	03	
10	11	12	13	
20	21	22	23	
30	31	32	33	

(columns)

Element indexes are typically defined in the format[x][y] [x] being the number of rows [y] being the number of columns For example: this array could be defined as array[4][4]

#### **Matrices**

## **Basic Matrix Operations**

- ► access X element in a matrix
- ► traversal of a matrix
- searching a matrix
- ► sorting a matrix

## Accessing the elements of a matrix

A = [[1, 2, 3], [4, 5, 6], [7,8,9]]

```
# Accessing certain elements in a matrix
print("1st_element_of_1st_row:", A[0][0])
print("2nd_element_of_the_2nd_row:", A[1][2])
print("2nd_element_of_3rd_row:", A[2][1])
```

# Accessing the elements of a matrix

```
A = [[1, 2, 3], [4, 5, 6], [7,8,9]]
# Traversing the matrix
for row in A:
    # Traversing the matrix
    for x in row:
        print(x, end=""")
    print()
```

# There are numerous applications of matrices

- ► Encryption: Matrices encrypt data into unreadable formats and decode it for secure communication.
- ➤ Computer Graphics: transformations like scaling, rotation, and translation of objects in 2D and 3D graphics
- ► Machine Learning: fundamental data structures for neural networks

- ► Economics and Business: optimize business operations like supply chains and financial forecasting
- Navigation Systems: GPS systems use matrices to calculate positions, distances, and directions in 2D and 3D space.
- ➤ Weather Prediction: Matrices solve systems of differential equations to model and predict climate and weather patterns
